The ability of compost to provide nutrients and to add some moisture to the soil should be evaluated when it is used as a fertilizer. An inquiry into the desirability of developing a standard for the composting of municipal solid waste is suggested. The author is a biotransformation specialist who has worked for the Environmental Protection Agency. Composting occurs when organic materials, such as plant waste, are treated with enzymes and bacteria that break down the waste. Composting will cause lysis of cells, cytotoxic effects, and precipitation of humic and fulvic acids. This study examined the potential adverse effects of composting of bovine waste on young broiler chickens. The thiobarbituric acid reactive substances method was used to analyze the effects of composting on bovine waste. The effects of composting on the chickens were examined by measuring body weight, organ weight, organ to body weight ratios, and histopathologic changes in various organs. The effects of bovine manure composting were also determined in a tetracycline-resistant strain of E. coli. The results indicated that bovine manure composting had minimal adverse effects on the chickens. Further research is needed to assess the effects of composting on a variety of animals. Composting is of great importance since it allows for the disposal of organic solid wastes in a useful and safe manner. This paper focuses on the treatment of organic solid waste by anaerobic composting. One important goal of composting is to minimize the generation of hazardous chemicals (e.g., pathogenic microbes, heavy metals, and persistent organic pollutants) and to increase the value of the biodegradable fraction of the c6a93da74d
